Moment Generating Function: used to calculate statistics for random variables (assume data sets are representative of statistical distribution of concentration) in solute transport.

1) Spatial Distribution - (plume)

- Sample many locations for a given time; 1 time snapshot (where is mass?)
- C varies in $\mathrm{X}, \mathrm{C}(\mathrm{x})$
- Gives distribution of plume
- Provides information on dimensions and location of solute
- Lagrangian Approach- move along with solute; primarily 2-D and 3-D focus

2) Temporal Distribution - $(\mathrm{BTC}=$ breakthrough curve $)$

- Sample many times at 1 location (when will mass arrive?)
- C varies with time $\mathrm{C}(\mathrm{t})$
- Arrival and travel time (velocity and distance).
- Provides information on arrival times of solute.
- Eulerian Approach- watch solute pass by; primarily 1-D

Moment Analysis: evaluates spatial or temporal properties (statistics) about a plume.

## 1-D Spatial (absolute) $M_{\underline{n}}$

```
(general) \(\mathrm{n}^{\text {th }}: \mathrm{M}_{\mathrm{n}}=\int \mathrm{cx}^{\mathrm{n}} \mathrm{dx}=\Sigma \mathrm{cx}^{\mathrm{n}} \Delta \mathrm{x}\)
    \(0^{\text {th }}: \mathrm{M}_{0}=\int \mathrm{cdx}=\Sigma \mathrm{c} \Delta \mathrm{x}\) (total mass)
    \(1^{\text {st: }}: \mathrm{M}_{1}=\int \operatorname{cxdx}=\Sigma \mathrm{cx} \Delta \mathrm{x}\) (mean location for the center of mass)
    \(2^{\text {nd }}: \mathrm{M}_{2}=\int \mathrm{cx}^{2} \mathrm{dx}=\Sigma \mathrm{cx}^{2} \Delta \mathrm{x}\) (spread of plume)
```

## 1-D Temporal (absolute) $M_{\underline{n}}$

(general) $\mathrm{n}^{\mathrm{th}}: \mathrm{M}_{\mathrm{n}}=\int \mathrm{ct}^{\mathrm{n}} \mathrm{dt}=\Sigma \mathrm{ct}^{\mathrm{n}} \Delta \mathrm{t}$
$0^{\text {th }}: \mathrm{M}_{0}=\int \mathrm{cdt}=\Sigma \mathrm{c} \Delta \mathrm{t}$ (total mass)
$1^{\text {st. }}: \mathrm{M}_{1}=\int \mathrm{ctdt}=\Sigma \mathrm{ct} \Delta \mathrm{t}$ (mean arrival time)
$2^{\text {nd }}: \mathrm{M}_{2}=\int \mathrm{ct}^{2} \mathrm{dt}=\Sigma \mathrm{ct}^{2} \Delta \mathrm{t}$ (degree of spreading)

Normalized ( $\mu_{\mathbf{n}}{ }^{\prime}$ ): (always divide by the $0^{\text {th }}$ moment $\mathrm{M}_{0}$ ); $\mathrm{dx}=$ spatial; $\mathrm{dt}=$ temporal (general) $\mu_{\mathrm{n}}{ }^{\prime}=\mathrm{M}_{\mathrm{n}} / \mathrm{M}_{0}=\int \mathrm{cx}^{\mathrm{n}} \mathrm{dx} / \int \mathrm{cdx}=\Sigma \mathrm{cx}^{\mathrm{n}} \Delta \mathrm{x} / \Sigma \mathrm{c} \Delta \mathrm{x}$

Central ( $\mu_{\mathrm{n}}{ }^{\mathrm{c}}$ ): (general); $\mathrm{dx}=$ spatial; $\mathrm{dt}=$ temporal

$$
\mu_{\mathrm{n}}^{\mathrm{c}}=\int\left(\mathrm{x}-\mu_{1}{ }^{\prime}\right)^{\mathrm{n}} \mathrm{cdx} / \int \mathrm{cdx}=\Sigma\left(\mathrm{x}-\mu_{1}\right)^{\mathrm{n}} \mathrm{cdx} / \Sigma \mathrm{c} \Delta \mathrm{x}
$$

Example of central ( $2^{\text {nd }}$ central or $2^{\text {nd }}$ central normalized)
$\mu_{2}{ }^{\mathrm{c}}=$ variance $=\sigma^{2}=\mathrm{M}_{2} / \mathrm{M}_{0}-\mu_{1}{ }^{\prime 2}=\int\left(\mathrm{x}-\mu_{1}{ }^{\prime}\right)^{2} \mathrm{cdx} / \int \mathrm{cdx}=\Sigma\left(\mathrm{x}-\mu_{1}{ }^{\prime}\right)^{2} \mathrm{cdx} / \Sigma \mathrm{c} \Delta \mathrm{x}$
$\mu_{2}{ }^{\mathrm{c}}=\mathrm{D} 2 \mathrm{t}$ or $\mathrm{d} \mu_{2} / \mathrm{dt}=2 \mathrm{D}$; Where D is Dispersion Coefficient
Moment accuracy decreases with increasing order ( $3^{\text {rd }}$ defines asymmetry or skewness).

## Spatial Moment

$\mathrm{M}_{0}=$ total mass (over distance)
Normalized $\mathrm{M}_{1}=$ average location of plume center
$\mathrm{M}_{2}=$ spread in distribution about that center
$\mathrm{d}\left(\right.$ normM $\left.\mathrm{m}_{1}\right) / \mathrm{dt}=\mathrm{dx} / \mathrm{dt}=$ velocity of plume

## Temporal Moment

$\mathrm{M}_{0}=$ total mass (through time)
Normalized $\mathrm{M}_{1}=$ average time of arrival of plume (get velocity if you know the center of distribution)
$\mathrm{M}_{2}=$ spread in time about that arrival time

## Calculating Moments

You can use either rectangular or trapezoidal integration to perform moment analysis with a data set. Trapezoidal integration is usually seen as more accurate, and is given here. The formulas for the zeroeth and first normalized temporal moments are given. For spatial moments and moments of higher order, solve for yourself from these formulas and the notes above.

Given a data set with $n$ number of concentration-time data points, beginning with point'1':
$\mu_{0}=\sum_{i=2}^{n}\left(\frac{C_{i}+C_{i-1}}{2}\right)\left(t_{i}-t_{i-1}\right)$
$\mu_{1}^{\prime}=\frac{\sum_{i=2}^{n}\left(\frac{t_{i} C_{i}+t_{i-1} C_{i-1}}{2}\right)\left(t_{i}-t_{i-1}\right)}{\mu_{0}}$
Mean Arrival Time (MAT): = First normalized temporal moment
Mean Travel Time (MTT): = MAT - Avg. Injection Time of Tracer Pulse

$$
=\mu_{1}^{\prime}-0.5 \mathrm{t}_{\mathrm{o}}
$$

where $t_{0}$ is the total injection time of tracer pulse. When solute mass balance is good (close to $100 \%$ ) the zeroeth moment can be used as $\mathrm{t}_{\mathrm{o}}$.
