## Calculating Oxide Weight Percents from Formulae and Normalizing Chemical Analyses <br> C:la-StudioClassroomlminex02.rtf; July 8, 2005 (4:12pm)

The atomic weights of elements tell us how many grams there are per mole. Likewise, the atomic weight of an oxide (or any compound) tells us how many grams there are per mole of the oxide/compound.

For example, the atomic weight of quartz, $\mathrm{SiO}_{2}$, is 60.0843 (=28.0855 + 2*15.9994; make sure you know where these numbers come from). So quartz weighs 60.0843 grams per mole. Each mole contains $6.022 \times 10^{23}$ (Avagodro's number) of molecules. So each $\mathrm{SiO}_{2}$ molecule weighs $60.0843 \div 6.022 \times 10^{23}=$ a very small number!

## Formulas to Weight percents (wt\%)

Suppose I asked you to tell me the wt \%s (weight percents) of $\mathrm{Li}, \mathrm{Al}$ and Si in spodumene, $\mathrm{LiAlSi}_{2} \mathrm{O}_{6}$. The calculation is as follows:

|  | $\mathrm{a}=$ <br> \# atoms in spod | $\mathrm{b}=$ <br> at wt elem | $\mathrm{c}=$ <br> $\mathrm{a} \times \mathrm{b}$ | $100 \times \mathrm{c} / \mathrm{d}=$ <br> wt $\%$ elem |
| :--- | ---: | ---: | ---: | ---: |
| ion | 1 | 6.941 | 6.94 | 3.73 |
| Li | 1 | 26.98154 | 26.98 | 14.50 |
| Al | 2 | 28.0855 | 56.17 | 30.18 |
| Si | 6 | 15.9994 | 96.00 | 51.59 |
| O |  |  | $\mathrm{d}=186.09$ | 100.00 |

==>Spodumene contains 3.7 wt\% Li, 14.5 wt\% Al, and 30.2 wt\% Si.
For reasons explained in the book, we report chemical analyses in terms of weight percents of the oxides. So, we could redo the above calculation as follows:

| ion | oxide | $a=$ <br> at wt oxide | $b=$ <br> \# oxides in <br> spod | $c=$ <br> $a \times b$ | $100 \times \mathrm{c} / \mathrm{d}=$ <br> wt $\%$ oxide in spod |
| :--- | ---: | ---: | ---: | ---: | ---: |
| Li | $\mathrm{Li}_{2} \mathrm{O}$ | 29.8814 | 0.5 | 14.94 | 8.03 |
| Al | $\mathrm{Al}_{2} \mathrm{O}_{3}$ | 101.9613 | 0.5 | 50.98 | 27.40 |
| Si | $\mathrm{SiO}_{2}$ | 60.0843 | 2 | 120.17 | 64.58 |
| TOTAL |  |  |  | $\mathrm{d}=186.09$ | 100.00 |

$==>$ So, spodumene contains 8.0 wt $\% \mathrm{Li}_{2} \mathrm{O}, 27.4$ wt $\% \mathrm{Al}_{2} \mathrm{O}_{3}$ and 64.6 wt $\% \mathrm{SiO}_{2}$.
(Make sure you know where all these numbers came from.)

## Wt\%s to Formulas

We can also do the reverse calculation. Suppose we have a mineral analysis that is $23.9253 \mathrm{wt} \% \mathrm{FeO}, 13.4217 \mathrm{wt} \% \mathrm{MgO}, 22.6359 \mathrm{wt} / \mathrm{Al}_{2} \mathrm{O}_{3}$ and $40.0170 \mathrm{wt} \% \mathrm{SiO}_{2}$. In the table below I show how to convert an analysis from oxide weight percent to a chemical formula. (See also Box 1.5 in the text for more explanation.)

| A | B | C | D | E | F | G | H | 1 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| oxide | at wt of oxide | \# cations in oxide | \# oxygen in oxide | mineral analysis | =E/B | cation | $\begin{array}{r} =\mathrm{F} \times \mathrm{C} \\ =\# \text { cations } \end{array}$ | $\begin{array}{r} =F \times D \\ =\text { \# oxygen } \end{array}$ |
| FeO | 71.8464 | 1 | 1 | 23.9253 | 0.3330074 | $\mathrm{Fe}+2$ | 0.333 | 0.333 |
| MgO | 40.3044 | 1 | 1 | 13.4217 | 0.3330074 | $\mathrm{Mg}+2$ | 0.333 | 0.333 |
| $\mathrm{Al}_{2} \mathrm{O}_{3}$ | 101.9613 | 2 | 3 | 22.6359 | 0.2220049 | Al+2 | 0.444 | 0.666 |
| $\mathrm{SiO}_{2}$ | 60.0843 | 1 | 2 | 40.0170 | 0.6660148 | $\mathrm{Si}+4$ | 0.666 | 1.332 |
|  |  |  |  |  |  |  | Oxygen = | 2.664 |

Study the above table and make sure you know where all the numbers come from.
Columns H and I allow us to write the following formula:

$$
\mathrm{Fe}_{0.333} \mathrm{Mg}_{0.333} \mathrm{Al}_{0.444} \mathrm{Si}_{0.666} \mathrm{O}_{2.664}
$$

This is a crummy looking formula because the subscripts are not integers.
After some trial and error, you will find an appropriate fudge factor to multiply everything by, and this formula becomes

$$
\mathrm{Fe}_{1.5} \mathrm{Mg}_{1.5} \mathrm{Al}_{2.0} \mathrm{Si}_{3.0} \mathrm{O}_{12}
$$

If you look this up in a book, after scrounging around for a while you will find that this is the formula of a garnet that is $50 \%$ almandine $\left(\mathrm{Fe}_{3} \mathrm{Al}_{2.0} \mathrm{Si}_{3.0} \mathrm{O}_{12}\right)$ and $50 \%$ pyrope $\left(\mathrm{Mg}_{3} \mathrm{Al}_{2.0} \mathrm{Si}_{3.0} \mathrm{O}_{12}\right)$.

Note that in real life, the math never comes out as exact as in the above examples (or the problems below). Analytical error introduces some uncertainty and adds difficulties to normalizations, but the approach and principles are still the same.

Your Problems
Be warned - these can be tricky!

1. Consider the mineral orthoclase with formula $\mathrm{KAlSi}_{3} \mathrm{O}_{8}$. What are the weight percents of $\mathrm{K}_{2} \mathrm{O}, \mathrm{Al}_{2} \mathrm{O}_{3}$ and $\mathrm{SiO}_{2}$ in orthoclase? Show all work, don't just look up the answers.
2. Suppose you conducted an analysis of an unknown mineral and found it contained the following weight percents:

| oxide | wt $\%$ |
| :--- | :--- |
| $\mathrm{Na}_{2} \mathrm{O}$ | 15.33079 |
| $\mathrm{Al}_{2} \mathrm{O}_{3}$ | 25.22062 |
| $\mathrm{SiO}_{2}$ | 59.44859 |
| TOTAL | 100 |

Normalize this analysis by using atomic weights to change it into a formula. You will have to goof around, but if you guess the number of oxygen correctly, all the other subscripts will come out to be integers. Name the mineral!
